

• Reminders:

- Program #2 due on Thursday, February 6th by 11:55pm
- Keep up with Zybooks assignments

14

Local Variables

- Local variable: variable that is assigned a value inside a function
 - Belongs to the function in which it was created
 - Only statements inside that function can access it, error will occur if another function tries to access the variable

13

- <u>Scope</u>: the part of a program in which a variable may be accessed
 - For local variable: function in which created

Local Variables

- A *local variable* cannot be accessed by statements inside its function which precede its creation
- Different functions may have local variables with the same name
 - Each function does not see the other function's local variables, so no confusion

Parameters = Local Variables

- "That sounds like local variables."
- Just as local variables are invisible outside of the function that owns them, variables used as parameters inside a function definition are local to that function.
- Parameters in a function definition are really local variables that are created and assigned values automatically when the function is called.

You've seen arguments already.

- name = input(<u>"What is your name?</u>")
- x = 5
- y = 2
- print(<u>"x is</u>", <u>x</u>, <u>"y is</u>", <u>y</u>)
- print("their sum is", x + y)

Arguments can be variables, literals, or math expressions.

18

In Class Example

• Using functions, write a program that prompts the user for 3 numbers and outputs the average of those numbers.

Tricky Example

def mystery(x, z, y):
 print(z, y-x)

def main(): x = 9 y = 2 z = 5 mystery(z, y, x) mystery(y, x, z) mystery(x + z, y - x, y) main()

Global Variables

- <u>Global variable</u>: created by assignment statement written outside all the functions
 - Can be accessed by any statement in the program file, including from within a function

DO NOT USE GLOBAL VARIABLES!

- Global variables making debugging difficult
 Many locations in the code could be causing a wrong variable value
- Functions that use global variables are usually dependent on those variables
- Makes function hard to transfer to another program
- Global variables make a program hard to understand!

Global Constants

- <u>Global constant</u>: global name that references a value that cannot be changed
 - OK to use global constants in a program
 - To simulate global constant in Python, create global variable and do not re-declare it within functions

Global	<pre># The following is used as a global constant to represent # the contribution rate. CONTRIBUTION_RATE = 0.05</pre>
Constant Example	<pre>def main(): gross_pay = float(input('Enter the gross pay: ')) bonus = float(input('Enter the amount of bonuses: ')) show_pay_contrib(gross_pay) show_bonus_contrib(bonus)</pre>
	<pre># The show_pay_contrib function accepts the gross # pay as an argument and displays the retirement # contribution for that amount of pay. def show_pay_contrib(gross): contrib = gross + CONTRIBUTION_RATE print('Contribution for gross pay: \$', \ format(contrib, ',.2f'), \ sep='')</pre>
	<pre># The show bonus_contrib function accepts the # bonus amount as an argument and displays the # retirement contribution for that amount of pay. def show bonus_contrib (bonus): contrib = bonus = CONTRIBUTION_RATE print('Contribution for gross pay: \$', \ format(contrib, ',.2f'), \ sep='')</pre>
	<pre># Call the main function. main()</pre>

Practice

- Modify singHappyBirthday.py

 You no longer have a twin. Now you have a sibling that is two years older than you, but you share the same birthday.
 Edit code so that sing_song now will print the lyrics but also print how old the person is.

 - Add a second parameter to sing_song called age.
 - _ Edit main() to ask for your age, as well as your name and sibling's
 - Edit the two calls to sing_song so appropriate ages are passed as arguments. _
- 2. Write a new Python program that asks the user to input 2 numbers and outputs the sum of those numbers.

- Use 2 functions
 main(): Prompts the user to enter 2 numbers and calls sum()
 sum(): Takes in 2 parameters and outputs the sum of those numbers
