Factorial Function

Write a function that computes the factorial of a number using a loop (for or while loop is fine).

Examples:

```
factorial(5) returns 120      #(1*2*3*4*5)
factorial(8) returns 40320   #(1*2*3*4*5*6*7*8)
```

3

Factorial Function

- A different view of the same problem
- $\text{fact}(1) = 1$
- $\text{fact}(2) = 1 * 2$
- $\text{fact}(3) = 1 * 2 * 3$
- $\text{fact}(4) = 1 * 2 * 3 * 4$
- $\text{fact}(5) = 1 * 2 * 3 * 4 * 5$
- Notice that each product involves computing the entire product on the row above.

4

Factorial Function

- $\text{fact}(1) = 1$
- $\text{fact}(2) = 1 * 2$
- $\text{fact}(3) = 1 * 2 * 3$
- $\text{fact}(4) = 1 * 2 * 3 * 4$
- $\text{fact}(5) = 1 * 2 * 3 * 4 * 5$

7

Factorial Function

- $\text{fact}(1) = 1$
- $\text{fact}(2) = 1 * 2$
- $\text{fact}(3) = 1 * 2 * 3$
- $\text{fact}(4) = 1 * 2 * 3 * 4$
- $\text{fact}(5) = 1 * 2 * 3 * 4 * 5$
- Let's reformulate the definition of a factorial to take advantage of this relationship.

Recursion

- A **recursive function** is a function that calls itself.
- Recursive functions are used to solve problems where the **solution to a problem involves solving a smaller version of the same problem.**

9

Recursive Functions

- 2 parts:
 - Base Case: How to solve the smallest version of the problem that we care about.
 - Recursive Case: How to reduce the bigger version of the problem to a smaller version.
 - In order to work, the recursive case (when applied over and over) must eventually reduce every size of the problem down to the base case.
- What are these 2 parts for factorial?

10

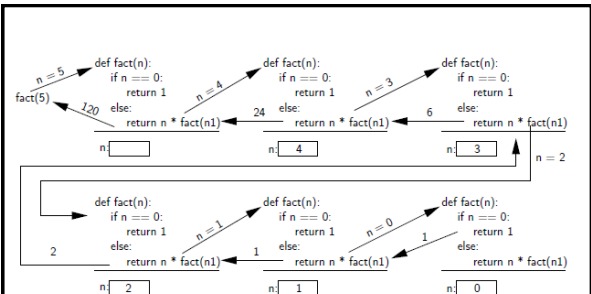

How does recursion work?

- Recursion works (in all modern programming languages) because:
 - All variables are local
 - The stack makes new memory for local variables every time a function is called
 - Let's look at the stack when we call fact(5).

12

Why is recursion useful?

- Any loop (for/while) can be replaced with a recursive function that does the same thing.
 - Some languages don't include loops!
- Because we started with Python and are moving onto C++, we naturally see things in terms of loops.
- Some problems have a “naturally” recursive solution that is hard to solve with a loop.
- Other problems have solutions that work equally well recursively or with loops (iteratively).

13

How to “get” recursion

An “instance” of a problem is a single occurrence of that problem.

- Forget all loops
- To find the base case:
 - “What’s the smallest version of this problem I would ever care about solving?”
- To find the recursive case:
 - “If I have an instance of the problem, how can I phrase how to solve the problem in terms of a smaller instance?”

14

Trust the recursion

- Base case is usually easy (When do I stop?)
- In recursive case:
 - Break the problem into two parts (not necessarily the same size):
 - A part I can solve “now”.
 - The answer from a smaller instance of the problem.
 - *Assume the recursive call does the right thing.*
 - Figure out how to combine the two parts.

15

3 Laws of Recursion

- A recursive algorithm must have a **base case**.
- A recursive algorithm must change its state and move toward the base case.
- A recursive algorithm must call itself, recursively.

Another Example

Write a recursive function to compute the sum of a list of numbers.

Iterative Solution:

```
def listsum(numList):
    theSum = 0
    for i in numList:
        theSum = theSum + i
    return theSum
```

We could rewrite the list as a fully parenthesized expression
 $((((1+3)+5)+7)+9)$

We can also parenthesize the expression the other way around,
 $(1+(3+(5+(7+9))))$

Notice that the innermost set of parentheses, $(7+9)$, is a problem that we can solve without a loop or any special constructs.

2/12/2015

CS 142: Object-Oriented Programming
Fall 2014

17

Sum of a List of Numbers

$total = (1+(3+(5+(7+9))))$

$total = (1+(3+(5+16)))$

$total = (1+(3+21))$

$total = (1+24)$

$total = 25$

Let's restate the sum problem in terms of Python lists.

The sum of the list `numList` is the sum of the first element of the list (`numList[0]`), and the sum of the numbers in the rest of the list (`numList[1:]`).

$listSum(numList) = first(numList) + listSum(rest(numList))$

So, what's our base case?

19

Practice

- Write a recursive function to compute a^b (a raised to the b power) where a and b are both positive integers.
- To solve this recursively, solve the recursive case and the base case.
- Assume there are no built-in functions that will do this operation.
- Examples:
 - `power_to(4, 3)` returns 64
 - `power_to(3, 5)` returns 243
